

# Shell Script

Shell: CLI (command line interface) which allows to interact with OS.  
when you give some command, it interprets your command and runs it.

## Shell Script:

- **writing multiple commands in series to automate process.**
- **e.g. taking backup of all the files and folders inside one folder**
- **shell script having extension .sh**
- **its a program but executes in shell environment**

Popular Shells: Bash, Zsh, Ksh, Fish

These are the popular shells inside we can run our shell scripts.

## Where we can use shell Scripts?

- Automate some process (backups, deployment)
- DevOps Workflow
- Entire System Management
- Environment Setup

## What is Bash?

Bash (Bourne Again Shell) is the most commonly used Unix/Linux Shell  
we can create variables, loops, functions, conditions etc..

Let's create one Script

```
#!/bin/bash
```

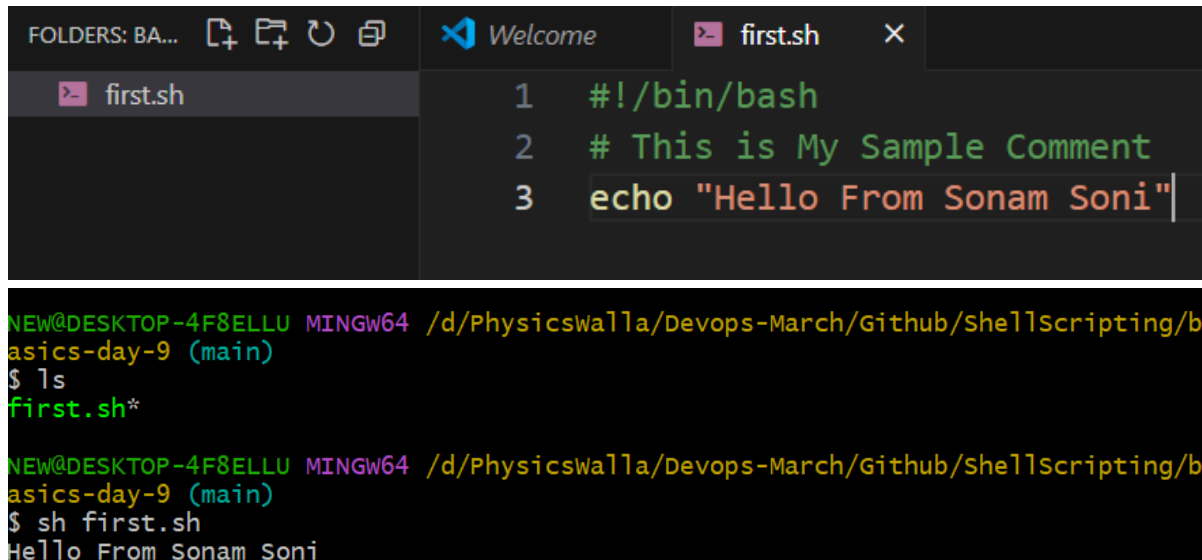

its called Shebang

it tells your system to use Bash Terminal to run script

If you will not write shebang then it will run in default terminal

**Comment in Script: Non executable statement called comment**

We can just use them for documentation/ understanding of code

The image shows a code editor window with a file named 'first.sh' open. The script contains three lines: a shebang, a comment, and an echo statement. Below the editor, a terminal window shows the script being listed and then executed, resulting in the output 'Hello From Sonam Soni'.

```
FOLDERS: BA... Welcome first.sh X
first.sh
1  #!/bin/bash
2  # This is My Sample Comment
3  echo "Hello From Sonam Soni"

NEW@DESKTOP-4F8ELLU MINGW64 /d/Physicswalla/Devops-March/Github/ShellScripting/basics-day-9 (main)
$ ls
first.sh*

NEW@DESKTOP-4F8ELLU MINGW64 /d/Physicswalla/Devops-March/Github/ShellScripting/basics-day-9 (main)
$ sh first.sh
Hello From Sonam Soni
```

## Variables::

In bash Variables is named location in memory which is used to store data temporary while executing script.

Special Variables

These variables already available no need to create and they have some special meanings

## Special Variables

# \$0 giving Script Name

# \$# giving No of Arguments you have passed

# \$@ show all arguments

# \$? showing status of exit

# \$1,\$2,\$3 to access individual arguments

**Means let's say i want to create one script which take 2 file names source and destination copy the the content**

**then how to take those file names from user?**

**we can take help of special variables where pass 2 arguments**

**sh copy.sh source.txt dest.txt**

**here total 2 arguments**

**\$0 : name of the file: copy.sh (script name)**

**\$# : total arguments : 2**

**\$@ show all arguments: source.txt dest.txt**

**\$? showing exit status of your program if 0 means program executed successfully, if 1 means exited with error**

**\$1 first argument : source.txt**

**\$2 second argument : dest.txt**
